What is meningitis?
Meningitis is a rare but potentially fatal bacterial or viral infection. It can result in permanent brain damage, learning disabilities, loss of limbs, loss of hearing, organ failure, and death. Meningitis is an inflammation of the membranes surrounding the brain and spinal cord.

Meningococcal bacterial meningitis strikes about 4,000 Americans each year and is responsible for approximately 500 deaths annually. It is estimated between 100-125 cases of meningococcal meningitis occur on college campuses and 5-15 students die each year as result.

What is the cause of meningitis?
Meningococcal meningitis is caused by the bacterium Neisseria meningitides. This bacterium is the leading cause of meningitis and septicemia (blood poisoning) among teenagers and young adults in the United States.

Why are college students at risk?
Meningococcal disease can affect people at any age. Studies show individuals between the ages of 15-24 are at a greater risk of contracting meningococcal meningitis. Due to lifestyle factors such as: crowded living situations, bar patronage, active or passive smoking, irregular sleep patterns, and sharing personal items. College students living in the residence halls are more likely to acquire meningococcal disease than the general college population.

How does meningitis spread?
Meningococcal meningitis is transmitted through the air via droplets of respiratory secretions (e.g. coughing, sneezing) or through direct contact with an infected person. Direct contact is defined as oral contact with shared items such as cigarettes, drinking glasses or through intimate contact such as kissing. Many people are carriers of the organism and are immune to infection; however, they can spread meningococcal meningitis to others.

What are the common symptoms?
Early symptoms resemble the flu and may include:
- High fever
- Headache
- Stiff neck
- Rash
- Nausea
- Vomiting
- Lethargy

Meningococcal meningitis is often mistaken as something that is less serious. If it is not detected early, often within hours of the first symptom(s), the disease can progress. Students are urged to seek medical care immediately if they experience two or more of the above symptoms concurrently.

When do outbreaks occur?
Meningococcal meningitis usually peaks during late winter and early spring.

How can meningitis be prevented?
A vaccine is available for the types of bacteria that cause meningococcal meningitis. These four types are serogroups A, C, Y and W-135 and account for 70 - 80% of meningococcal meningitis cases among the college population. The development of immunity post-vaccination usually requires 7 - 10 days. It is recommended the following people obtain the vaccination:

- Entering college students who want to decrease their risk for the disease
- Highest priority should be for students 18-24 years of age; students 25 years or older have a much lower risk of contracting the disease
- Students with medical conditions that compromise immunity (e.g., HIV, absent spleen, antibody deficiency)
- Students traveling to areas of the world with endemic meningococcal meningitis.

The Centers for Disease Control recommends college students become educated about meningococcal meningitis and the benefits of the vaccination.
How effective is the vaccine?
● It is 85% - 100% effective in preventing the disease among serogroups A, C, Y, and W-135 in older children and adults.
● Immunity lasts approximately 3 - 5 years

Where can one get the vaccine?
The meningitis vaccine is available at OU Health Services. For more information regarding the vaccine please call (405) 325-4611, ext. 56039.
