In connection with the works concerning dissociation of imaginal disks subjected to the action of trypsin solution, it was of interest to discover "survivability" of these disks under conditions of different concentrations of trypsin solution. For this purpose leg imaginal disks were chosen from the larvae of D. melanogaster of the "Berlin wild" line at the age of 72 hours and were put into trypsin solutions of different dilutions. 0.25% trypsin solution was used as an initial material to prepare the working solutions of 1:1, 1:2, and 1:8 in physiologic Ringer's solution (NaCl 7.500 g, KCl 0.287 g, CaCl₂·H₂O 0.287 g, distilled water to 1.0 liter). After 5 minutes' treatment of imaginal disks by trypsin solution at room temperature they were washed for one minute with 20% solution of bull serum prepared on the basis of Ringer's solution. Using the standard techniques of transplantation of imaginal disks (1), the latter were transplanted into larvae of the same age and line. In the control, selected disks of the same age were exposed for 5-10 minutes in Ringer's solution and then transplanted into the larval hosts.

For further analysis only those larvae were used that survived for 4 hours after transplantation, since the mortality in the first hours is presumed to be conditional on the imperfection of surgical techniques (2). The larval hosts with implanted disks were placed in tubes with the standard forage for drosophila (agar, raising, treacle) and kept at room temperature. Part of these larvae were allowed to pupate and imagos emerged. The adult flies were dissected and the presence of disk-implants was established. These disks were examined under a microscope to determine the elements of leg tissue. Results are given in Table 1.

Table 1. "Survivability" of leg imaginal disks after treatment with trypsin solution of different dilution.

This table shows that the increase of dilution of trypsin solution led to the increase of "survivability" of disks, both with regard to adult flies and with regard to surviving larvae; but at the same time this increase did not yield a concrete result in respect to the number of flies concerning surviving larvae. We are inclined to explain all this by unregistered technical conditions of operation rather than by peculiarities of the given trypsin dilution. In the selected disks we did not discover any significant qualitative difference (for example, appearance of allotypical elements) between the experimental and control groups.

3.4) it was interesting to find out whether the feature of behavior of mutation sn on the homeo-
erotic structures is retained at different temperatures. For this purpose homeotic mutants Nasobemia (Ns,3-48.0) and aristapeda (ssa,3-58.5) (its three alleles: ssak, ssaax and ssa40a) (transform antennae to the legs of mesothoracic type) were used. The number of large bristles was significantly more in mutants Ns. The double mutants sn;Ns and sn;ssaa obtained at 17, 25 and 28°C and single mutants sn, Ns and ssa were studied by binocular microscope (increase 12.5 x 4.0). 100 individuals of every genotype were tested to estimate penetrance, 64 to estimate expressivity.

The effect of temperature on the degree of twisting of bristles in mutants sn was not de-
tected. Twisting of bristles in mutants Ns and ssa was not found at different temperatures. Twisting of bristles on thoracic legs and antennal homeotic limbs was observed at the inter-
action of homeotic mutations Ns and ssa (its three alleles) with the mutation sn at all tem-
peratures (16, 25 and 28°C). The complete penetrance of this effect was observed. The degree of its expression on homeotic structures was identical to that on the corresponding segments of thoracic legs. In particular, twisting of bristles was significantly more marked in double
mutants sn;Ns on the homeotic structures than in mutants sn;ssa. It can be explained by the predominance of large bristles on homeotic limbs in mutants sn;Ns. The effect of temperature on the degree of twisting of bristles in double mutants was not found. The coincidence of ex-
pressivity of mutation sn on homeotic structures with that on the corresponding segments of
thoracic legs independent of temperature points out the morphogenetic relationship of elements (bristles) of homeotic and normal structures.

Kemphues, K.J. and T.C. Kaufman. Indiana University, Bloomington, Indiana. Two-
dimensional gel analysis of total proteins from X/O, X/Y, X/Y/Y, X/Y5 and X/YL
testes from D. melanogaster. An attempt to identify proteins specific to the Y
chromosome of D. melanogaster utilized the NEPHGE two-dimensional gel electrophoresis sys-
tem of O'Farrell (1977), as modified by Waring (1978), to display total proteins extracted from
testes. These gels offer the best one-step meth-
ood for visualizing a large array of proteins. In
these experiments, resolution of more than 300 spots from total proteins of [35S] methionine
labeled adult testes was possible.

Careful comparisons of autoradiographs of gels of labeled proteins from X/O, X/Y, X/Y/Y,
X/Y5 and X/YL testes were made. These comparisons revealed no consistent differences in the
two-dimensional pattern of proteins from testes of the various genotypes, other than an in-
crease in the intensity of labeling of five spots from X/Y/Y testes relative to other geno-
types. No protein differences, either qualitative or quantitative, were found between the au-
toradiographs of X/O and X/Y testes.

One basic protein of 55,000 daltons, however, did fail to appear in gels of testes from
two of the four X/O stocks examined. A two-dimensional gel analysis of protein from X/Y tes-
tes at various developmental stages (24 hour intervals, starting at 72 hours after egg deposi-
tion) showed that the 55,000 dalton protein was not synthesized until late in development (220
hours; late pupa). The late synthesis of this protein suggests that some triggering event is
necessary prior to synthesis. Because X/O spermatids degenerate before maturation (Kiefer 1970),
it is possible that the 55,000 dalton protein appears in some X/O testes and not in others be-
cause this degeneration could begin either before or after this triggering event due to differ-
ences in genetic backgrounds or culture conditions.

These results indicate that if the Y chromosome fertility factors are expressed as pro-
teins, the detection of these proteins will require more elaborate techniques than those de-
scribed here. These experiments also demonstrate that the Y chromosome functions in a subtle
manner which does not involve the regulation of synthesis of the major protein components of
spermiogenesis. However, it may be possible that the Y specific proteins contain no methion-
one and that other labeling procedures will allow for their detection.
