Gupta, A.P.<sup>†</sup> Harvard University, Cambridge, Massachusetts. [Present address: Cidade Universitaria UFRJ, Rio de Janeiro, Brazil.] A new technique for collecting *Drosophila* eggs.

Generally, *Drosophila* eggs are collected by having flies oviposit in bottles on spoons containing food medium or in petri dishes on colored food medium. The well fed adults are usually allowed to oviposit 24 to 48 hours to collect an adequate egg sample. It is difficult to collect eggs of sufficient sample size from a number of crosses or strains simultaneously. To facilitate collecting large egg samples from a number of crosses simultaneously over a short period of time, I modified the prevailing techniques with excellent results. The success of this technique depends upon starving the flies shortly before permitting them to oviposit.

25-30 pairs of newly emerged *D. pseudoobscura* were allowed to mate in vials for 5-10 days at 24°C under optimal rearing conditions. They were then transferred to empty half-pint milk bottles for 45-90 minutes at room temperature. The time of starvation is determined by noting when the activity of the flies diminishes. At this time, a teaspoon containing Carpenter's medium with food coloring and covered with a tin layer of dead or live Fleishmann's yeast suspension is put into the bottle. If dead yeast is used, prepare the solution 2-3 days before use. The thin layer of yeast suspension is allowed to dry before the spoon is put into the bottle. The back of the spoon must fit firmly against the side of the bottle to prevent females ovipositing between the spoon and the bottle. The spoons with large numbers of eggs are removed after 6-14 hours.

It would appear that the starved females retain their eggs until they once again are able to feed. At that time they lay their eggs in profusion. For a research project, I had to collect 1800 fertile eggs for each of two parental and two F<sub>1</sub> classes, for a total of 7200 eggs, to be tested simultaneously. Using this technique, I had no trouble in collecting the required number of eggs in a short period of time. The technique was further tested using 25-30 pairs of *D. melanogaster*. Approximately 1000-2000 eggs were collected in 1-3 hours. Thus this method is probably useful for collecting large numbers of eggs in a number of species in a short period of time.
